AI decision models arrive in the SOC market: what security leaders should weigh

A new class of AI "decision" models appeared within a month, from TypeSafe AI, OpenAI and Cribl, and is now relevant to AI-driven SOC platforms. The source excerpt is brief and gives few details.

- TypeSafe AI released a model called Jev on September 15, describing it as a "System One" model, a reference to fast, intuitive thinking.
- OpenAI announced a Decisions API at DevDay and opened a public beta on October 6.
- Cribl published cribl-decision, an open LoRA adapter that can be run locally.
- The article links this new model category to the design of AI SOC platforms.
- The available excerpt does not describe performance, pricing or security testing.

What was reported

According to The Hacker News, a new category of AI model moved from nonexistent to widespread in about a month. TypeSafe AI released Jev on September 15 and positioned it as a System One model, borrowing Kahneman's term for fast, intuitive thinking. OpenAI announced a Decisions API at DevDay, with a public beta opening on October 6. Cribl published cribl-decision, an open LoRA adapter that organisations can run locally. The article notes other entrants as well, but the excerpt is cut short.

Why it matters for SOC leaders

The article frames these models as relevant to AI SOC platforms, where automated triage and decisions are becoming a selling point. The excerpt does not give benchmarks, accuracy claims or details of how the models are built into products, so no conclusions about quality or risk should be drawn from it alone.

For regulated institutions, the practical question is governance rather than adoption speed. A model that makes or recommends decisions on alerts needs clear ownership, testing and oversight, particularly where it is a hosted API versus a locally run adapter, since data handling differs between the two.

Suggested stance

Treat this as a development to monitor. Read the full article and vendor documentation before any evaluation, and keep any pilot limited, supervised and reversible.

What to do now

1. Read the full source article and vendor documentation before drawing conclusions.
2. Ask SOC platform vendors whether they use decision models and whether they are hosted or run locally.
3. Confirm where alert and log data is processed and stored before enabling any AI decision feature.
4. Require human review of AI-driven triage decisions during any pilot.
5. Record AI-assisted SOC decisions in your risk register and review them against NCA ECC and SAMA CSF requirements.
