FBI Seizes Seven Domains Tied to Flax Typhoon Infrastructure Scanning Tools

The FBI and US DoJ say they disrupted tools used by China-linked group Flax Typhoon, seizing domains and blocking platforms used to scan, and sometimes infiltrate, US critical infrastructure.

- The FBI and US Department of Justice announced a disruption of tools used by Flax Typhoon, an advanced persistent threat group linked to China.
- Seven domains were seized, according to the headline.
- Access to platforms used to scan, and in some cases infiltrate, US critical infrastructure was blocked.
- The source excerpt does not list the seized domains or give technical indicators.

The U.S. Federal Bureau of Investigation and Department of Justice have announced action against tooling

used by Flax Typhoon, an advanced persistent threat group the source describes as China-linked.

What was done

According to the report, the agencies seized domains, with the headline putting the number at seven, and blocked access to platforms the group used. These were employed to scan U.S. critical infrastructure and, in some cases, to infiltrate it. The excerpt we reviewed cuts off before listing the seized domains, so we cannot confirm which domains or platforms are affected.

Why it matters for Saudi institutions

The report concerns U.S. targets, and it does not mention any activity in the Kingdom. Even so, it is a reminder that actors of this kind begin with scanning of exposed systems before any intrusion. Operators of critical infrastructure and regulated institutions in Saudi Arabia may wish to confirm that their own exposed assets are understood and monitored. A takedown also does not end a group's activity, and infrastructure can be rebuilt.

Suggested approach

No specific vulnerability or indicator is given in the source, so there is nothing to patch on this basis alone. The practical step is to review external exposure and detection, and to watch for the full list of seized domains from official U.S. releases so it can be checked against logs.

What to do now

1. Review the inventory of internet-facing assets and close or restrict anything not needed.
2. Check that logging and alerting cover inbound scanning and reconnaissance against exposed services.
3. Obtain the official list of seized domains from U.S. authorities when published and search proxy, DNS and firewall logs for matches.
4. Confirm that OT and IT environments in critical infrastructure are segmented and that remote access is controlled.
5. Brief the security operations team and confirm the escalation path to the relevant sector regulator.
